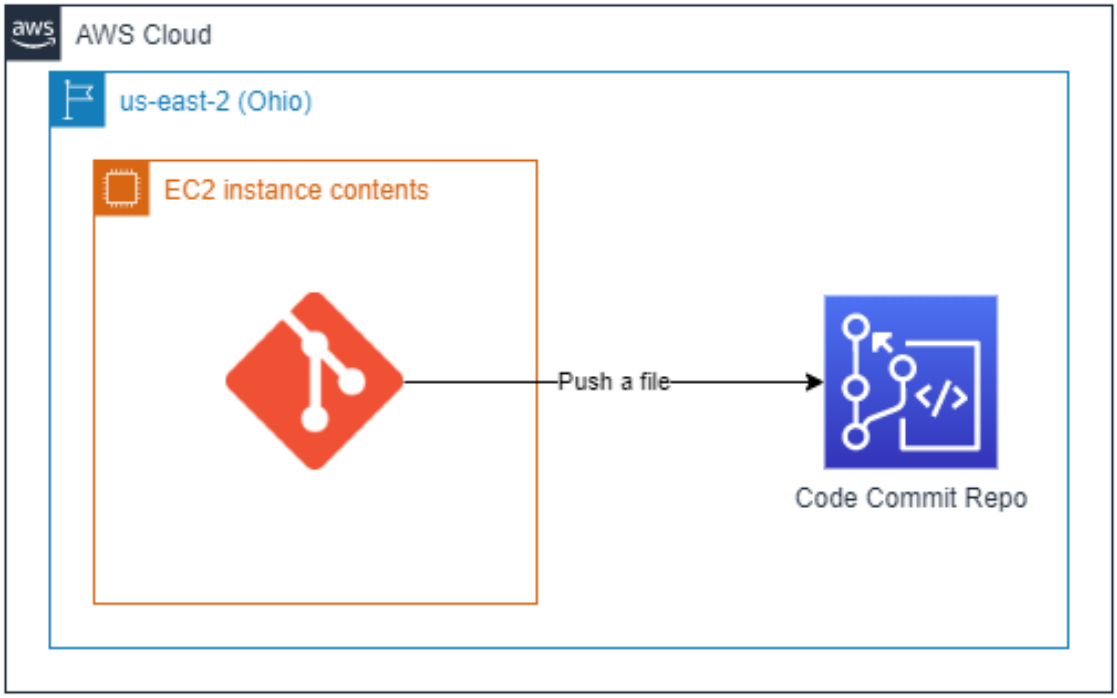
1. Creating Local Repositories with Git and Adding/Checking in Files

1.1 Description

Git is a free and open source distributed version control system designed to handle everything from small to very large projects with speed and efficiency. Before writing any code, you need to create a CodeCommit repository, clone it locally, add a README.md file, commit the file, and push it to CodeCommit.

1.2 Architecture Diagram

The diagram below displays a visual representation of the application architecture:



1.3 Lab Steps

Follow the steps outlined below to achieve the objective of this lab exercise:

1. Create a CodeCommit Repository and copy the clone URL (HTTPS) for future use.
2. Create an EC2 Instance (Amazon Linux 2) and SSH into it via Sessions Manager Option.
   Note: Make sure the role **CCL-EC2-Role** is attached to the instance, only then can you select the Sessions Manager Option.
3. Change user to super user or root user and change directory to **~**
4. Make sure Git is installed, if not install Git. Then perform the following configurations:

```
git config --global user.name "<Some Name>"
```

```
git config --global user.email "<some email">
```

5. Navigate to **IAM** > **Users** > **Your UserName** > **Security Credentials** > **HTTPS Git Credentials** for CodeCommit. Here generate credentials and save them.
6. Clone the created repo by pasting the copied URL from Step 1.
7. Change directory to the created repo
8. Create a new file with some content and perform the following steps:

```
git add <filename>
```

```
git commit -m "<Some commit message>"
```

```
git push origin master
```

9. Go to the created repo and check if the pushed file is available there.

1.4 Troubleshooting

S. No	Problem	Solution
1	Not able to SSH into the Instance	Make sure the role **CCL-EC2-Role** is attached to the instance.
2	Not able to clone the repository	Make sure that you followed Step 5 properly
